

## Clarion, the Web, OOP and You

### Building a Web Site with Clarion for Windows

Tom Hebenstreit  
Consulting Services

---

---

---

---

---

---

---

---

## Introduction

- ◆ Leveraging your current skills to create powerful web sites
- ◆ Gathering and displaying information interactively
- ◆ Using Clarion to write WWW scripts
- ◆ Using Templates to simplify your Web programs
- ◆ Using OOP to simplify using web objects

---

---

---

---

---

---

---

---

## Topics to Cover

- ◆ World Wide Web Basics
- ◆ Communicating with a Web Server
- ◆ Processing Input
- ◆ Creating Web Pages dynamically
- ◆ Transferring Files to/from the web

---

---

---

---

---

---

---

---

## Web Basics

- ◆ HTTP - the language of the Web
- ◆ Hyper Text Markup Language (HTML) - the language of browsers
- ◆ What is a web page?
  - Static Pages
  - Dynamic Pages
- ◆ Cookies

---

---

---

---

---

---

---

## How the web works

- ◆ Browser request via URL or link (HTTP)
- ◆ The Web server figures out what to do
  - Static Pages
    - » Server finds page (file) and sends it back
  - Dynamic Pages/Links
    - » Server runs your program, which creates a pages and passes it back to the server
    - » Server returns page created by your program
- ◆ Browser parses/displays the page (HTML)

---

---

---

---

---

---

---

## Linking your programs with the Web Server

- ◆ IDC (Internet Database Connector)
- ◆ Standard CGI (Common Gateway Interface)
- ◆ Win-CGI (CGI adapted to Windows)
- ◆ ISAPI (Internet Server Application Program Interface)
- ◆ Other methods (ADO, ActiveX, JDBC, etc.)

---

---

---

---

---

---

---

## Internet Database Connector (IDC)

- ◆ Advantages
  - No programming required
  - Uses HTX files
- ◆ Disadvantages
  - Limited control
  - Requires ODBC connection
  - Basic knowledge of SQL needed
  - Developed for IIS

---

---

---

---

---

---

---

## WIN-CGI

- ◆ Adapted from CGI to overcome limited Windows support for Unix methods
- ◆ Advantages
  - Simple interface, no API calls
  - Programs can do whatever you want
- ◆ Disadvantages
  - Limited support under IIS
  - Programs load/unload each time they are run
  - Extensive use of temp files to pass information

---

---

---

---

---

---

---

## Standard CGI

- ◆ Developed for use on Unix Web Servers
- ◆ Advantages
  - Supported by virtually all servers
  - Use environment to pass information
  - Programs can do whatever you want
- ◆ Disadvantages
  - Programs load/unload each time they are run
  - Must use API calls to get Form data

---

---

---

---

---

---

---

## Internet Server Application Program Interface (ISAPI)

- ◆ Proprietary - developed by Microsoft for IIS
- ◆ Advantages
  - Runs in Server program space
  - Fast response
- ◆ Disadvantages
  - Very complicated to program to natively
  - Clarion is not 'thread safe'

---

---

---

---

---

---

---

## Using Tornado/ISAPI

- ◆ Tornado OCX mediates between Clarion and ISAPI
- ◆ Advantages
  - Fast
  - Supports HTX (no writing HTML)
  - Run multiple instances of program
- ◆ Disadvantages
  - Must purchase Tornado OCX
  - Requires ISP to install OCX on server

---

---

---

---

---

---

---

## Gathering Information: Web Queries and Forms

- ◆ Creating the Form
- ◆ Linking to or invoking your program
- ◆ 'GET' versus 'POST'
- ◆ Field Types
  - Entry
  - Checkboxes
  - Options
  - Drop lists
  - Multi-line Text area

---

---

---

---

---

---

---

## Validating Web Form Input

- ◆ Very limited control over input
- ◆ MaxLength for Entry fields
- ◆ No browser limits on TextArea fields
- ◆ Checking can only be done after Submit
  - Checking before your program using JavaScript, VBscript, Java, etc.
    - » Not supported by all browsers
  - Checking within your program

---

---

---

---

---

---

---

---

## Basic Tools for Web Work

- ◆ Clarion for Windows 32-bit
- ◆ Some knowledge of HTML
- ◆ A Web Page authoring program
- ◆ A Web Browser (preferably Netscape, IE and an older browser)
- ◆ A Web Server for Testing

---

---

---

---

---

---

---

---

## Writing a Clarion Script

- ◆ Be aware of target Web Server
- ◆ Choose the method to use
  - Speed, standardization, simplicity
- ◆ Create your Application
  - Process Requests and Form Data
  - Creating Pages to Return

---

---

---

---

---

---

---

---

## Processing a Web Request: GET

- ◆ All information is passed in the 'Query String' field as one long string
- ◆ Query String is 'URL Encoded'
  - Basic format is Field=Value
  - Spaces converted to '+'
  - Non-standard characters are passed as 'Escape Sequences'

---

---

---

---

---

---

---

## Example: URL Encoding

- ◆ Raw Form Data
  - Name=Bob Smith!
  - Phone=(310) 111-2222
- ◆ URL Encoded
  - Name=Bob+Smith%21&Email=%28310%29+111-2222
- ◆ Templates, etc., provide methods to automatically decode (be sure to use them!)

---

---

---

---

---

---

---

## Processing a Web Form: POST

- ◆ Information is passed in Field=Value pairs
- ◆ Must retrieve each field individually
- ◆ Field data may need to be 'cleaned up' (remove escape sequences, etc.)
- ◆ How options and checkboxes are passed
- ◆ Creating a 'Cancel' option

---

---

---

---

---

---

---

## Creating Pages to Send Back

- ◆ Process the input request
- ◆ Decide what to do with it
- ◆ Return something
  - Forms
  - Tables of records
  - Handling errors or missing data
    - » Using 'Back' versus a URL/Link

---

---

---

---

---

---

---

## Creating Pages: Writing HTML line by line

- ◆ Works with all methods (Win-CGI, CGI, Tornado/ISAPI)
- ◆ Must understand basics of HTML
- ◆ Your script creates the entire page via HTML hard-coded into the program
- ◆ Changing the page means changing the program

---

---

---

---

---

---

---

## Creating Pages: Using an HTX file

- ◆ HTX file exists totally separate from your program
- ◆ No HTML knowledge required
- ◆ Create string of '<%field%>=data' pairs to pass to server
- ◆ Web Server combines HTX file and your variables into an HTML page to send back

---

---

---

---

---

---

---

## Creating Pages: Using Psuedo HTX

- ◆ Pre-designed Web Page is stored in Memo or ASCII File
- ◆ Perform your own 'merge' of data and HTML
- ◆ Read, process and write each line
- ◆ Program does not need recompile for simple changes to page

---

---

---

---

---

---

---

## Real Life

*Examples of working applications*

---

---

---

---

---

---

---

## FTP - File Transfer Protocol

- ◆ Used to transfer files between computers linked via the Internet
- ◆ Bi-directional - both upload and download
- ◆ Operates in a client/server fashion
- ◆ Must have User Name/Password to login
- ◆ Anonymous FTP allows anyone to access a site (or a portion of one)
- ◆ Transfers always initiated by the client

---

---

---

---

---

---

---

## Transferring Files via FTP

- ◆ Manual/Interactive methods
  - Via your online service (AOL or CSI)
  - Using a dedicated program (CuteFTP, etc.)
  - Win 95 FTP command line
- ◆ Automated
  - Win 95 FTP program via batch file
  - Adding FTP to your programs using WinInet.DLL

---

---

---

---

---

---

---

## Using WININET FTP Services

- ◆ Establishing the connection
- ◆ Retrieving directory Listings
- ◆ Working with directories
- ◆ Working with files
  - Upload/Download
  - Rename, Delete, Etc.
- ◆ Ending the session
- ◆ Other services (HTTP, Cookie, Gopher)

---

---

---

---

---

---

---

## Examining the Code, Classes and Templates

- ◆ Win-CGI Examples
  - Classes
- ◆ CGI Examples
  - Classes
- ◆ Tornado/ISAPI Examples
  - Output classes

---

---

---

---

---

---

---

## Learning More...

- ◆ Study the examples
- ◆ Books
  - *Up to date list provided at DevCon*
- ◆ Web Sites
  - *Up to date list provided at DevCon*
- ◆ Other resources

---

---

---

---

---

---

---

## Summary

- ◆ You can create scripts as simple or complicated as you want using Clarion.
- ◆ You can write your own HTML or avoid it completely
- ◆ You can write, compile, test and debug all on one machine
- ◆ Using the provided Templates and examples -- IT'S EASY!!

---

---

---

---

---

---

---

## Questions

- ◆ Ask away!

**\* Thank you for attending! \***
